(57) **ABSTRACT**

A physically unclonable function (PUF) includes a plurality of PUF elements to generate an N-bit PUF signature. For each bit in the N-bit PUF signature, a PUF group of K number of individual PUF elements indicating a single-bit PUF value is used to generate a group bit. The group bits are more repeatable than the individual PUF elements. The value K may be selected such that (K+1)/2 is an odd number.

## GROUPING OF PHYSICALLY UNCLONABLE FUNCTIONS

### FIELD

The present disclosure relates to electronic security and in particular, to physically unclonable functions.

### BACKGROUND

In various electronic devices and systems, physically unclonable functions (PUF) are used to generate unique signatures that are unfeasible to replicate and cannot be predicted. Certain values generated in a PUF may exhibit instability over time, which is a source of undesired error.

### BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 illustrates a system used in conjunction with at least one embodiment;

FIG. 2 illustrates a processor used in conjunction with at least one embodiment;

FIG. 3 illustrates a physically unclonable function generator used in conjunction with at least one embodiment;

FIG. 4 illustrates an electronic system used in conjunction with at least one embodiment;

FIG. 5 illustrates one embodiment of a method for evaluating a physically unclonable function;

FIG. 6 illustrates one embodiment of a method for initializing a physically unclonable function; and

FIG. 7 illustrates a prior art physically unclonable function.

### DESCRIPTION

Embodiments of the invention pertain to the use of PUFs to authenticate and identify individual integrated circuits (ICs, also referred to as “chips” and/or “semiconductor devices”). In at least one embodiment, an electronic device includes a plurality of PUF elements to indicate a corresponding plurality of single-bit PUF values, signature logic to generate an N-bit PUF signature, and an output to read the PUF signature. In some embodiments, the PUF signature includes a group bit from each of N groups of the plurality of PUF elements and a value of the group bit for a PUF group indicates a value associated with a majority of the PUF elements in the PUF group.

In some embodiments, the value of the group bit for a PUF group is determined based on values of a subset of the PUF elements in the PUF group. Embodiments of the subset of PUF elements include PUF elements that indicate a first majority value during an initial reading of the signature logic. The value of the group bit for a PUF group may, in some embodiments, be determined by a second majority value indicated by a majority of PUF elements in the subset. Some embodiments generate and store a mask indicating which PUF group elements comprise the subset of PUF elements and to store the first majority value. In some embodiments, each of the PUF groups includes K hits, where K is an integer greater than 0. In at least one embodiment,  $(K+1)/2$  is an odd integer. In at least one embodiment, a PUF may be characterized in terms of its entropy and noise rate where the entropy is an indicator of how likely any give PUF will be a 1-majority or 0-majority device and the noise rate is an indicator of how likely it is that a 1-majority device exhibits a 0 state. In at least one embodiment, the PUFs described have an entropy exceeding 80% and a noise rate in the range of approximately 5-10%.

2

In at least one embodiment, a processor includes a plurality of PUF elements to indicate a corresponding plurality of single-bit PUF values and PUF signature logic to generate an N-bit PUF signature. In some embodiments, the PUF signature includes a group bit from each of N groups of the plurality of PUF elements. In some embodiments, a value of the group bit for a PUF group is determined based on values of PUF elements in the PUF group. In at least one embodiment, a value of the group hit for a PUF group is determined based on values of a subset of the PUF elements in the PUF group. In some embodiments, the subset of PUF elements includes PUF elements that indicated a first majority value for the PUF group during an initial or previous reading of the PUF signature logic. A value of the group bit for a PUF group may, in some cases, be determined by a second majority value comprising a value indicated by a majority of PUF elements in the subset.

In at least one embodiment, the processor includes a PUF register to store an indication of PUF data including an initial PUF signature generated by the PUF signature logic during an initial reading and a mask indicating which PUF elements in the PUF group belong to the subset of PUF elements. In some embodiments, each PUF group includes K PUF elements where  $(K+1)/2$  is an odd integer and wherein a number of bits in the mask is limited to  $(K+1)/2$ .

In at least one embodiment, a computer system includes a processor and a memory accessible to the processor. The processor includes a plurality of PUF elements to indicate a corresponding plurality of single-bit PUF values and signature logic to generate an N-bit PUF signature. In some embodiments, the PUF signature includes a group bit from each of N groups of the plurality of PUF elements, wherein a value of the group bit for a PUF group is determined based on values of PUF elements in the PUF group, and wherein each of the PUF groups includes K bits, where K is an integer greater than 0. The computer system may be implemented in a platform such as a mobile platform that includes tablet devices, smartphones, and so forth. In at least one of these embodiments, the computer includes a touchscreen controller to manage client based input.

PUFs may be employed in a variety of applications, including, but not limited to, anti-counterfeiting, anti-tampering, inventory management, network access control, and cryptography. For such purposes, PUFs may be used in integrated circuits to generate an output that is unique to an individual instance of a manufactured part. In this manner, a PUF may be used to identify individual chips and/or to distinguish chips of the same type from one another.

In some embodiments, the value of a PUF for authentication lies in the unclonable nature of the PUF response. This unclonable feature results from a dependency of the PUF response on physical attributes of the underlying semiconductor device. For example, a PUF may exploit variability in process physics associated with the manufacture of a semiconductor device, which may result in randomized physical dimensions or material composition that give rise to an unpredictable PUF response. In another example, a PUF device may exploit existing physical features, such as surface roughness of a material layer in a semiconductor device, to obtain random variability in an electronic output signal.

Other desirable features for authentication include ease and/or speed of obtaining the PUF response, as well as low cost. PUFs may accordingly be implemented in a number of different types of semiconductor devices including a field-programmable gate array (FPGA), a programmable logic device (PLD), a digital signal processor (DSP), a microprocessor, static random access memory (SRAM), flip-flop tran-

sistors, radio frequency identification tags (RFIDs), optical devices, and/or application specific integrated circuits (ASICs), among others. Integrated circuits may use a PUF response as an internal security key and perform various authentication functions. In certain instances, the PUF response and related operations may be completely hidden from external entities. In this manner, a PUF element on a chip may enable authentication without the use of cryptography, which may be complex and expensive to implement and operate.

An inherent advantage of authentication elements is that PUFs are generally quite tamper resistant. Any effort to contact or otherwise access a PUF physically will change the physical nature of the PUF and affect the PUF behavior or value. Thus a PUF is resistant against physical intrusion.

Thus, while PUFs provide for a randomly unique marking of a chip, a desirable feature for a PUF is reproducibility and/or stability of the PUF response. In other words, the same PUF challenge should produce the same PUF response on a given PUF, irrespective of other factors. In practice, most PUF circuits will not achieve complete reproducibility, though the variability in the PUF response may be very small, such that the PUF remains useful for an intended authentication purpose. The variation in the PUF response may arise from thermal and/or electronic instability and may be overcome, at least to a degree, with external error correction techniques that may rely on so-called "helper data" to ensure a consistent PUF response. As will be described herein, a method and apparatus for reducing the variability of a PUF response is economical, secure, and may be used with different kinds of PUFs.

In the following description, details are set forth by way of example to facilitate discussion of the disclosed subject matter. It should be apparent to a person of ordinary skill in the field, however, that the disclosed embodiments are exemplary and not exhaustive of all possible embodiments.

Throughout this disclosure, a hyphenated form of a reference numeral refers to a specific instance of an element and the un-hyphenated form of the reference numeral refers to the element generically or collectively. Thus, for example, widget 12-1 refers to an instance of a widget class, which may be referred to collectively as widgets 12 and any one of which may be referred to generically as a widget 12.

Embodiments may be implemented in many different system types. Referring now to FIG. 1, a block diagram of selected elements of a processor system in accordance with an embodiment of the present disclosure is shown. FIG. 1 shows a system in which processors, memory, and input/output devices are interconnected by a number of point-to-point (P-P) interfaces, as will be described in further detail. However, in other embodiments (not shown in FIG. 1) the processor system may employ different bus architectures, such as a front side bus, a multi-drop bus, and/or another implementation. Although one processor is depicted in the example embodiment of FIG. 5 for descriptive clarity, in various embodiments, the point-to-point system architecture shown in FIG. 5 may be implemented with two processors. It is further noted that, in some embodiments, different numbers of processors may be employed using elements of the depicted architecture.

In the FIG. 1 embodiment, processor system 100 is a point-to-point interconnect system that includes processor 170. In the FIG. 1 embodiment, processor 170 is a multi-core processor including a plurality of cores 174, which may vary in number in individual implementations, as desired. As shown, a portion of processor 170 including cores 174 may be referred to as core portion 178, while a portion of processor

170 including other elements, yet excluding cores 174, may be referred to as uncore portion 180. In different embodiments (not shown in FIG. 1), a varying number of cores may be present in a particular processor. Cores 174 may comprise a number of sub-elements (not shown in FIG. 1), also referred to as clusters, that provide different aspects of overall functionality. For example, cores 174 may each include a memory cluster (not shown in FIG. 1) that may comprise one or more levels of cache memory. Other clusters (not shown in FIG. 1) in cores 174 may include a front-end cluster and an execution cluster.

In the FIG. 1 embodiment, processor 170 includes PUF 173 that generates a PUF signature with improved repeatability, as will be described in further detail herein.

In particular embodiments, cores 174 within processor 170 may not communicate directly with each other, but rather, may communicate via crossbar 171, which may include intelligent functionality such as cache control, data queuing, P-P protocols, and multi-core interfacing. Crossbar 171 may thus represent an intelligent uncore controller for uncore portion 180 that interconnects cores 174 with memory controller hub (MCH) 172, last-level cache memory (LLC) 175, and P-P interface 176, among other elements. In particular, to improve performance in such an architecture, cache controller functionality within crossbar 171 may enable selective caching of data within a cache hierarchy including LLC 175 and/or one or more caches present in cores 174. In certain embodiments (not shown), crossbar 171 includes a memory management unit that handles access to virtual memory addresses and maintains at least one translation lookaside buffer (not shown in FIG. 1) for improved performance with regard to memory access.

In the FIG. 1 embodiment, LLC 175 may be coupled to processor cores 174 as a shared resource such that a memory access instruction from any single core 174 may invoke LLC 175. Additionally, MCH 172 may provide for direct access by processor 170 to memory 132 via memory interface 182. For example, memory 132 may be a double-data rate (DDR) type dynamic random-access memory (DRAM) while memory interface 182 and MCH 172 comply with a DDR interface specification. Memory 132 may represent a bank of memory interfaces (or slots) that may be populated with corresponding memory circuits for a desired DRAM capacity.

Processor 170 may also communicate with other elements of processor system 100, such as I/O hub 190 and I/O controller hub 118, which are also collectively referred to as an ellipse that supports processor 170. P-P interface 176 may be used by processor 170 to communicate with I/O hub 190 via interconnect link 152. In certain embodiments, P-P interfaces 176, 194 and interconnect link 152 are implemented using Intel QuickPath Interconnect architecture.

In the embodiment of FIG. 1, I/O hub 190 includes interface 192 to couple I/O hub 190 with first bus 116, which may support high-performance graphics and/or video output to corresponding bus devices, such as graphics 138. Graphics 138 may represent a high-performance graphics engine that outputs to a display device (not shown in FIG. 1). In one embodiment, first bus 116 is a Peripheral Component Interconnect (PCI) bus, such as a PCI Express (PCIe) bus and/or another computer expansion bus or interface. I/O hub 190 may also be coupled to I/O controller hub 118 at interface 196 via interconnect link 156. In certain embodiments, interface 196 is referred to as a south bridge. I/O controller hub 118 may provide I/O interconnections for various computer system peripheral devices and interfaces and may provide backward compatibility with legacy computer system peripheral devices and interfaces. Thus, I/O controller hub 118 is shown

5

providing network interface **130** and audio I/O **132**, as well as, providing interfaces to second bus **120**, third bus **122**, and fourth bus **121**, as will be described in further detail.

Second bus **120** may support expanded functionality for microprocessor system **100** with I/O devices **112**, and may be a PCI-type computer bus. Third bus **122** may be a peripheral bus for end-user consumer devices, represented by desktop devices **124**, communication devices **126**, and touchscreen controller **127**, which may further include various types of keyboards, computer mice, communication devices, data storage devices, bus expansion devices, device controllers, etc. For example, touchscreen controller **127** may represent a controller for a touchscreen included with processor system **100**. In certain embodiments, third bus **122** represents a Universal Serial Bus (USB) or similar peripheral interconnect bus. Fourth bus **121** may represent a computer interface bus for connecting mass storage devices, such as hard disk drives, optical drives, and disk arrays, which are generically represented by data storage **128**, shown including code **129** that may be executable by processor **170**.

Embodiments may be implemented in code and may be stored on a storage medium having stored thereon instructions which can be used to program a system to perform the instructions. The storage medium may include, but is not limited to, any type of disk including floppy disks, optical disks, compact disk read-only memories (CD-ROMs), compact disk rewritables (CD-RWs), and magneto-optical disks, semiconductor devices such as read-only memories (ROMs), random access memories (RAMs) such as dynamic random access memories (DRAMs), static random access memories (SRAMs), erasable programmable read-only memories (EPROMs), flash memories, electrically erasable programmable read-only memories (EEPROMs), magnetic or optical cards, or any other type of media suitable for storing electronic instructions.

Referring now to FIG. 2, a block diagram of selected elements of one embodiment of a processor **200** is shown. Processor **200** may be a multi-core processor including a plurality of processor cores. In FIG. 2, processor **200** is shown including core **202**, which may be representative for a plurality of cores, when present. It is noted that other elements of processor **200** besides core **202** may be referred to as an uncore. Although a singular core is depicted in the example embodiment of FIG. 2 for descriptive clarity, in various embodiments, a different number of cores may be employed using elements of the depicted architecture. Core **202** may comprise a number of sub-elements, also referred to as clusters, that provide different components of overall functionality. For example, core **202** may include front-end **204**, execution engine **206**, and core cache **208**.

In FIG. 2, front-end **204** may be responsible for fetching instruction bytes and decoding those instruction bytes into micro-operations that execution engine **206** and/or core cache **208** consume. Thus, front-end **204** may be responsible for ensuring that a steady stream of micro-operations is fed to execution engine **206** and/or core cache **208**. Execution engine **206** may be responsible for scheduling and executing micro-operations and may include buffers for reordering micro-operations and a number of execution ports (not shown in FIG. 2). Core memory **208** may include multiple levels of a cache hierarchy. In various embodiments, core cache **208** may include a first level cache (not shown) that may correspond to an L0 cache. Core cache **208** may further include mid-level cache (not shown) that may correspond to an L1 cache in some embodiments.

In particular embodiments, core **202** within processor **200** is not equipped with direct means of communicating with

6

another core (not shown), but rather, communicates via crossbar **214**, which may include intelligent functionality such as cache control, data queuing, P-P protocols, and multi-core interfacing. Crossbar **214** may thus represent an intelligent uncore controller that interconnects core **202** with LLC **216**, among other elements (not shown) of processor **200**.

In the FIG. 2 embodiment, processor **200** includes LLC **216**, which may be a higher-level cache that operates in conjunction with core cache **208**, which may further include a first level cache and a mid-level cache (not shown). Thus, LLC **216**, along with core cache **208**, may represent a part of a cache hierarchy. During operation, memory requests from execution engine **206** may first access core cache **208** before looking up any other caches within a system. Accordingly, for improved performance, frequently accessed data may be present in the lowest possible cache level, i.e., core cache **208**. When the requested data is not present in core cache **208**, a request may be issued to LLC **216**, which may be a shared cache among a plurality of cores (not shown in FIG. 2). In the FIG. 2 embodiment, processor **200** is shown including PUF **273**, which generates a PUF signature with improved repeatability, as will be described in further detail herein.

Advancing now to FIG. 3, selected elements of an embodiment of PUF generator **300** are illustrated. As shown, PUF generator **300** depicts elements that may be used to generate PUF signature **304** in an electronic device, such as a processor, while preventing errors generally associated with PUFs due to instability, according to the methods described herein.

In the FIG. 3 embodiment, PUF generator **300** includes PUF **302**, which includes individual PUF elements **306** that produce single-bit PUF values. It is noted that PUF elements **306** may be any of a variety of different types of PUFs, as mentioned previously. Instead of a direct one-to-one correspondence of PUF elements **306** to individual bits in PUF signature **304** (see FIG. 7, prior art), PUF generator **300** is implemented with K-number of PUF elements **306** that comprise PUF group **310**, from which a corresponding group bit is used as a constituent bit in PUF signature **304**. In this manner, a single bit in PUF signature **304** may be determined based on K-number of values of PUF elements **306** in corresponding PUF group **310**, which may improve an overall repeatability of PUF signature **304**, as compared with a repeatability of individual PUF elements **306**.

In FIG. 3, PUF **302** is shown with N-number of PUF groups **310**, each PUF group **310** having K-number of PUF elements **306**. For example, 1<sup>st</sup> PUF group **310-1** is shown having PUF elements **306-1** to **306-K**. Similarly, 2<sup>nd</sup> PUF group **310-2** and N-th PUF group **310-N** also have K-number of PUF elements **306** each (not marked in FIG. 3), respectively.

In operation of PUF generator **300**, signature logic **308** may respond to receiving challenge input **312** by generating one bit of PUF signature **304** for each PUF group **310**. Thus, 1<sup>st</sup> PUF group **310-1** may result in PUF signature bit **304-1**, 2<sup>nd</sup> PUF group **310-1** may result in PUF signature bit **304-2**, and so on, up to N-th PUF group **310-N**, which may result in PUF signature bit **304-N**. The improvement in repeatability of PUF signature **304** may be achieved because a collective repeatability of PUF group **310** for a single bit value (e.g., a majority value) may be greater than a repeatability for individual PUF element **306**. The improvement in repeatability may be sustained over various operating conditions, such as voltage and temperature, that PUF generator **300** is subject to. It is noted that PUF generator **300** is implemented with K+N number of PUF elements **306**. Challenge input **312** may represent any of a variety of input signals, triggers, codes, instructions, and/or bit patterns that signature logic **308** is implemented to recognize. In certain embodiments, chal-

7

challenge input **312** may be a restricted input and/or may itself be subject to various security or authentication methods (not described herein). It is further noted that PUF signature **304**, shown as an output value in FIG. 3, may not be stored by PUF generator **300**, but may be generated and transmitted on request, such as on receipt of challenge input **312**. In this manner, PUF **302** may represent a unique source for PUF signature **304** in an electronic device implementing PUF generator **300**.

Turning now to FIG. 4, selected elements of an embodiment of electronic system **400** are illustrated. In the FIG. 4 embodiment, electronic system **400** depicts a general implementation of PUF generator **300**, described above with respect to FIG. 3. In the FIG. 4 embodiment, requestor **420** may be an entity that seeks to obtain a PUF signature from electronic device **402**, which includes PUF generator **300**, and therefore, is also unclonable. Although shown as a separate entity, in certain embodiments (not shown) requestor **420** may be a component included in electronic device **402**. For example, when electronic device **402** is a processor, requestor **420** may represent another component included in the processor. Accordingly, electronic system **400** may describe implementations where a PUF signature is provided externally and/or internally to electronic device **402**. In operation, requestor **420** may issue challenge **416** to electronic device **402** and receive, in response, response **418**, which may include a PUF signature (not shown in FIG. 4, see FIG. 3). PUF generator **300** may receive challenge **416** (or another challenge input **312** derived from challenge **416**, see FIG. 3) as an indication and/or request to generate the PUF signature. PUF generator **300** may then generate the PUF signature, such as PUF signature **304** in FIG. 3. In generating the PUF signature, PUF generator **300** may access memory media **408** for storing and retrieving PUF mask data **410**, which may include helper data, as will be described in further detail herein. In certain embodiments, memory media **408** and/or PUF mask data **410** may be integrated within PUF generator **300** (not shown). Once PUF generator **300** has generated the PUF signature, the PUF signature may be included in response **418**. It is noted that various other implementations of PUF generator **300** within electronic system **400** may be realized within the scope of the present disclosure.

Turning now to FIG. 5, a flow chart describing selected elements of an embodiment of method **500** for generating an N-bit length PUF signature based on groups of PUF elements is illustrated. It is noted that operations in method **500** may be omitted or rearranged in different embodiments, as desired. Method **500** may be executed, at least in part, by PUF generator **300** including signature logic **308** (see FIG. 3).

Method **500** may begin by reading (operation **502**) K-group bits from a first group of N-groups of PUF bits. It is noted that K may be an integer greater than zero. In particular embodiments, K may further be restricted to values where  $(K+1)/2$  is an odd number. Values of K and/or N may be defined when PUF generator **300** is designed and/or manufactured. A K-bit length mask may be applied (operation **504**) with the K-group bits to generate a group product, while the mask may have at least  $(K+1)/2$  masking bits and may correspond to the first group. Application of the mask may include multiplication of the mask value with the K-group bits when the group bit is 1. When the group bit is 0, application of the mask may first include inversion of the K-group bits followed by multiplication with the mask. The mask referenced in operation **504** may be generated prior to execution of method **500**, for example, by performing method **600** (see FIG. 6). For the purposes of describing method **500**, it will be assumed that the masking bits in the mask are true bits, although in

8

another embodiment (not shown) the mask may be used with reversed polarity. Among the bits corresponding to the masking bits, a number of true bits are counted (operation **506**) from the group product. Again, for the purposes of descriptive clarity, method operations **506** and **508** arbitrarily reference true bits, but in different embodiments (not shown), false bits may be alternatively referenced in method **500**. Next, a decision may be made (operation **508**) whether the number of true bits counted from the masked group product are a majority among the masking bits. When the result of operation **508** is YES, then the group bit is set (operation **510**) to true. When the result of operation **508** is NO, then the group bit is set (operation **512**) to false.

To further illustrate method **500**, a specific example of generating a single PUF group where  $K=5$  will now be described. First, the value of the K-group bits read in operation **502** will be given by  $\{0, 0, 1, 0, 0\}$ . During an initialization or set-up phase that is performed prior to method **500** (see method **600**, FIG. 6), it will be determined that the majority bit for this PUF group is 0 and the mask for this PUF group is  $\{1, 1, 0, 1, 1\}$ , where 1 s in the mask are masking bits that mark the location of the group bit (0) in the PUF group. Since the mask will be stored by PUF generator **300** and is retrievable, a complete stored mask with up to K number of masking bits may represent a security threat, since access to such mask data could enable reconstruction of the PUF signature. Therefore, to provide for extra security, the number of masking bits in the mask may be limited to  $(K+1)/2$  bits, or in this example, 3 bits. Therefore, the stored mask may actually have the value  $\{1, 1, 0, 1, 0\}$  (or another permutation of the complete mask with only 3 masked bits). Then, after inverting the K-group bits to  $\{1, 1, 0, 1, 1\}$  because the initial group bit was 0, the mask  $\{1, 1, 0, 1, 0\}$  may be applied in operation **504** to result in a masked group product  $\{1, 1, 0, 1, 0\}$ , where 1 s now represent false (0) bits in the original K-group bits due to the inverting. Counting, in operation **506**, the 1<sup>st</sup>, 2<sup>nd</sup>, and 4<sup>th</sup> bits in the K-group bits, we see that these three values are all 0, so the number of true bits is not a majority in operation **508**. Accordingly, the group bit is set to false (0) in operation **512**. It is noted that when any one zero bit in the K-group bits read in this example in operation **502** becomes inverted over time, the method will yield the same result.

Turning now to FIG. 6, a flow chart describing selected elements of an embodiment of method **600** for generating and storing a K-bit length mask as helper data is illustrated. It is noted that operations in method **600** may be omitted or rearranged in different embodiments, as desired. Method **600** may be executed, at least in part, by PUF generator **300** including signature logic **308** (see FIG. 3). It is noted that method **600** may be executed at least once prior to execution of method **500** (see FIG. 5).

Method **600** may begin by reading (operation **602**) K-group bits from a first group of N-groups of PUF bits. A majority bit among the K-group bits may be determined (operation **604**). For each bit in the K-group bits having a value equal to the majority bit, a corresponding bit in the mask may be set (operation **606**) to true. The mask for the first group may be stored (operation **608**). The mask stored in operation **608** may be retrieved and used for operation **504** in method **500**.

Advancing now to FIG. 7, selected elements of an embodiment of prior art PUF generator **700** are illustrated. As shown, PUF generator **700** depicts elements that may be used to generate prior art PUF signature **706** in an electronic device. In the FIG. 7 embodiment, PUF generator **700** includes prior art PUF **702**, comprised of N-number of PUF elements **704**, each indicating a binary value. As shown in prior art FIG. 7,

9

PUF element **704-1** is directly used for PUF signature bit **704-1**, PUF element **704-2** is directly used for PUF signature bit **706-2**, and so on, up to PUF element **704-N**, which is directly used for PUF signature bit **706-N**. Thus, in prior art PUF generator **700**, any variability in PUF elements **704** will directly result in variability of PUF signature **706**, which is a source of undesired error in PUF signature **706**.

To the maximum extent allowed by law, the scope of the present disclosure is to be determined by the broadest permissible interpretation of the following claims and their equivalents, and shall not be restricted or limited to the specific embodiments described in the foregoing detailed description.

What is claimed is:

1. A processor comprising:

a plurality of physically unclonable function (PUF) elements to indicate a corresponding plurality of single-bit PUF values;

signature logic to generate an N-bit PUF signature, wherein the N-bit PUF signature includes a group bit from each of N groups of the plurality of PUF elements, and wherein a value of the group bit for a PUF group is to indicate a value associated with a majority of the PUF elements in the PUF group, each of the N groups of the plurality of PUF elements including more than one PUF element; and

an output to read the N-bit PUF signature.

2. The processor of claim 1, wherein the value of the group bit for a PUF group is to be determined based on values of a subset of the PUF elements in the PUF group.

3. The processor of claim 2, wherein the subset of PUF elements includes PUF elements that indicated a first majority value during an initial reading of the signature logic.

4. The processor of claim 3, wherein the value of the group bit for a PUF group is to be determined by a second majority value comprising a value indicated by a majority of PUF elements in the subset.

5. The processor of claim 4, further comprising an output to:

store a mask to indicate which PUF group elements comprise the subset of PUF elements; and  
store the first majority value.

6. The processor of claim 1, wherein each of the PUF groups includes K bits, where K is an integer greater than 0.

7. The processor of claim 6, wherein  $(K+1)/2$  is an odd integer.

8. The processor of claim 1, wherein the N-bit PUF signature is repeatable at a higher reliability than at least some of the plurality of PUF elements.

9. A processor, comprising:

a plurality of physically unclonable function (PUF) elements to indicate a corresponding plurality of single-bit PUF values;

PUF signature logic to generate an N-bit PUF signature, wherein the N-bit PUF signature includes a group bit from each of N groups of the plurality of PUF elements,

10

wherein a value of the group bit for a PUF group is to be determined based on values of a subset of PUF elements in the PUF group; and  
an output to receive the N-bit PUF signature generated by the PUF signature logic.

10. The processor of claim 9, wherein the subset of PUF elements includes PUF elements that indicated a first majority value for the PUF group during a previous reading of the PUF signature logic.

11. The processor of claim 10, wherein the value of the group bit for a PUF group is to be determined by a second majority value comprising a value indicated by a majority of PUF elements in the subset.

12. The processor of claim 11, further comprising a PUF register to store an indication of PUF data including an initial PUF signature generated by the PUF signature logic during an initial reading and a mask to indicate which PUF elements in the PUF group belong to the subset of PUF elements.

13. The processor of claim 12, wherein each PUF group includes K PUF elements where  $(K+1)/2$  is an odd integer and wherein a number of bits in the mask is limited to  $(K+1)/2$ .

14. The processor of claim 13, wherein  $(K+1)/2$  is an odd integer.

15. A system comprising:

a processor;

a touchscreen controller; and

a memory accessible to the processor;

wherein the processor comprises:

a plurality of physically unclonable function (PUF) elements to indicate a corresponding plurality of single-bit PUF values;

and

signature logic to generate an N-bit PUF signature, wherein the N-bit PUF signature includes a group bit from each of N groups of the plurality of PUF elements, wherein a value of the group bit for a PUF group is to be determined based on values of a subset of PUF elements in the PUF group, and wherein each of the PUF groups includes K PUF elements, where K is an integer greater than 0.

16. The system of claim 15, wherein the subset of PUF elements includes PUF elements that indicated a first majority value for the PUF group during a previous reading of the signature logic.

17. The system of claim 16, wherein the value of the group bit for a PUF group is to be determined by a second majority value comprising a value indicated by a majority of PUF elements in the subset.

18. The system of claim 17, further comprising an output to:

store a mask to indicate which PUF elements in the PUF group comprise the subset of PUF elements; and  
store the first majority value.

19. The system of claim 18, wherein the mask is limited to  $(K+1)/2$  bits for indicating PUF elements.

20. The system of claim 19, wherein  $(K+1)/2$  is an odd integer.
